Spermatogenesis involves the differentiation of spermatogonial stem cells into spermatocytes via mitotic cell division and the production of haploid spermatids from the tetraploid primary spermatocytes via meiotic cell division. Spermatids subsequently give rise to spermatozoa in the final phase of spermatogenesis, called spermiogenesis.

The swelling of the posterior ends of the sperm flagella observed in some of the species is also of interest, and in this regard the viviparous clinids offer an excellent subject for comparative studies of sperm length, energetic of propulsion, and survival of the sperm.

Results of the present study indicate that there is not a smaller testes size in the hybrid compared with the purebred foxes and, therefore, this is not the determinant of impaired spermatogenesis. There were smaller diameters of the seminiferous tubules in the hybrids as compared with the purebred foxes, however, and this was associated with the disrupted spermatogenic processes in the hybrids.
